# Caching 101

## Why Cache?

---

- Large attack surface. Shared across cores/sockets.
- Fast. Can be used to build high-bandwidth channels
- Many states. Can encode secrets spatially to further improve bandwidth and precision.
- There exist many cache-like structures. The same attack concepts and tricks will apply.

**The Goal:**  
**Monitor access patterns at cache set/line  
granularity**

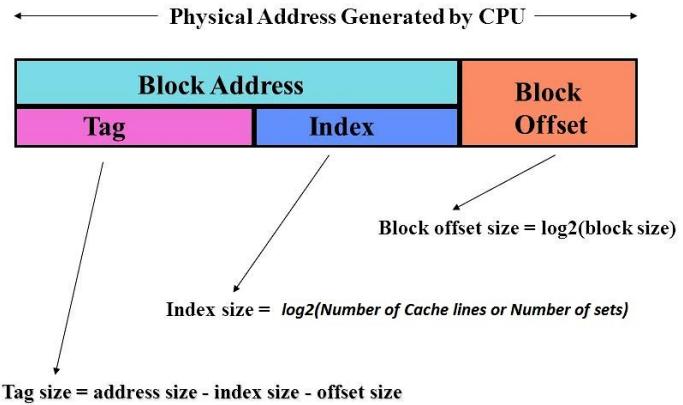

# Goal

---

- Attacker wants to learn which *cache sets/lines the victim accessed*

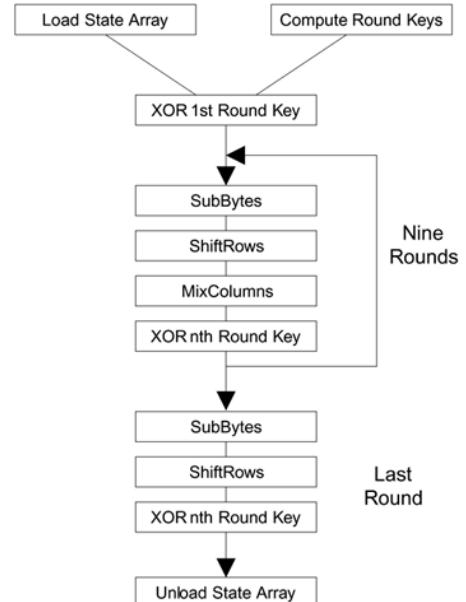

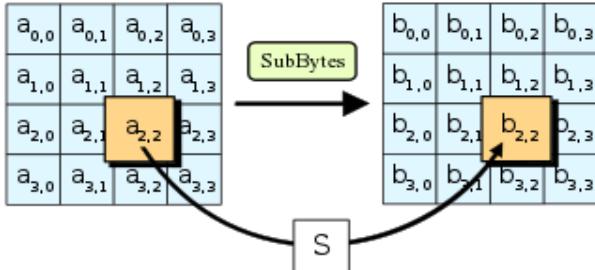

```
int secret=0xDEADBEEF  
int *ptr=&secret;  
int x=*ptr;
```

- Can reveal sensitive information

# Leaking Crypto Algorithm : AES

- AES implementations can use table lookups
  - S-Box substitutions
  - T-tables

# Leaking Crypto Algorithm: RSA

- Square-and-Multiply Exponentiation

Input :

base  $b$

modulo  $m$

exponent  $d = (d_{n-1} \dots d_0)_2$

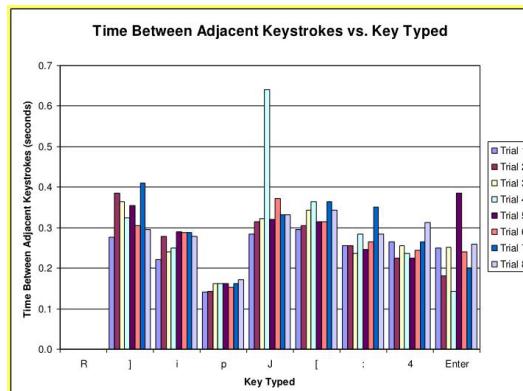

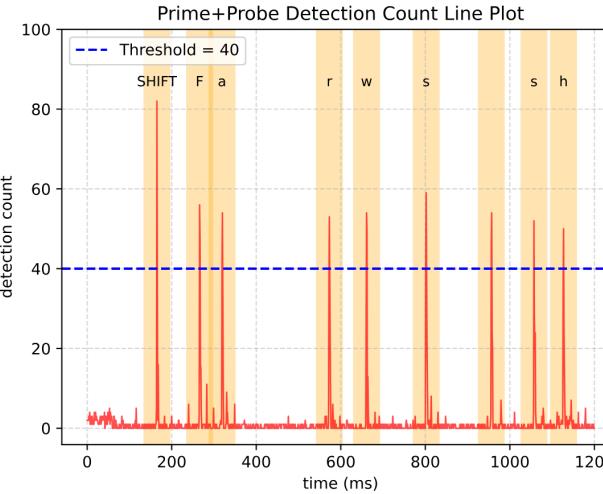

Output:

$b^d \bmod m$

```
r = 1
for i = n-1 to 0 do
    r = sqr(r)
    r = mod(r, m)
    if di == 1 then
        r = mul(r, b)
    r = mod(r, m)
end
end
```

# Keystroke Extraction

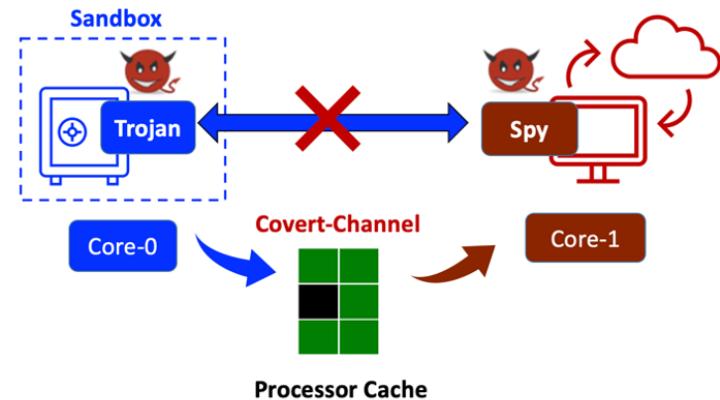

- Keystroke cadence yields keystroke extraction
- Monitor cacheline that registers keystrokes
  - Victim will access that cacheline every time he types a character

## Covert Channel

---

- Two processes can communicate over cache covert channel
- Useful for Spectre!

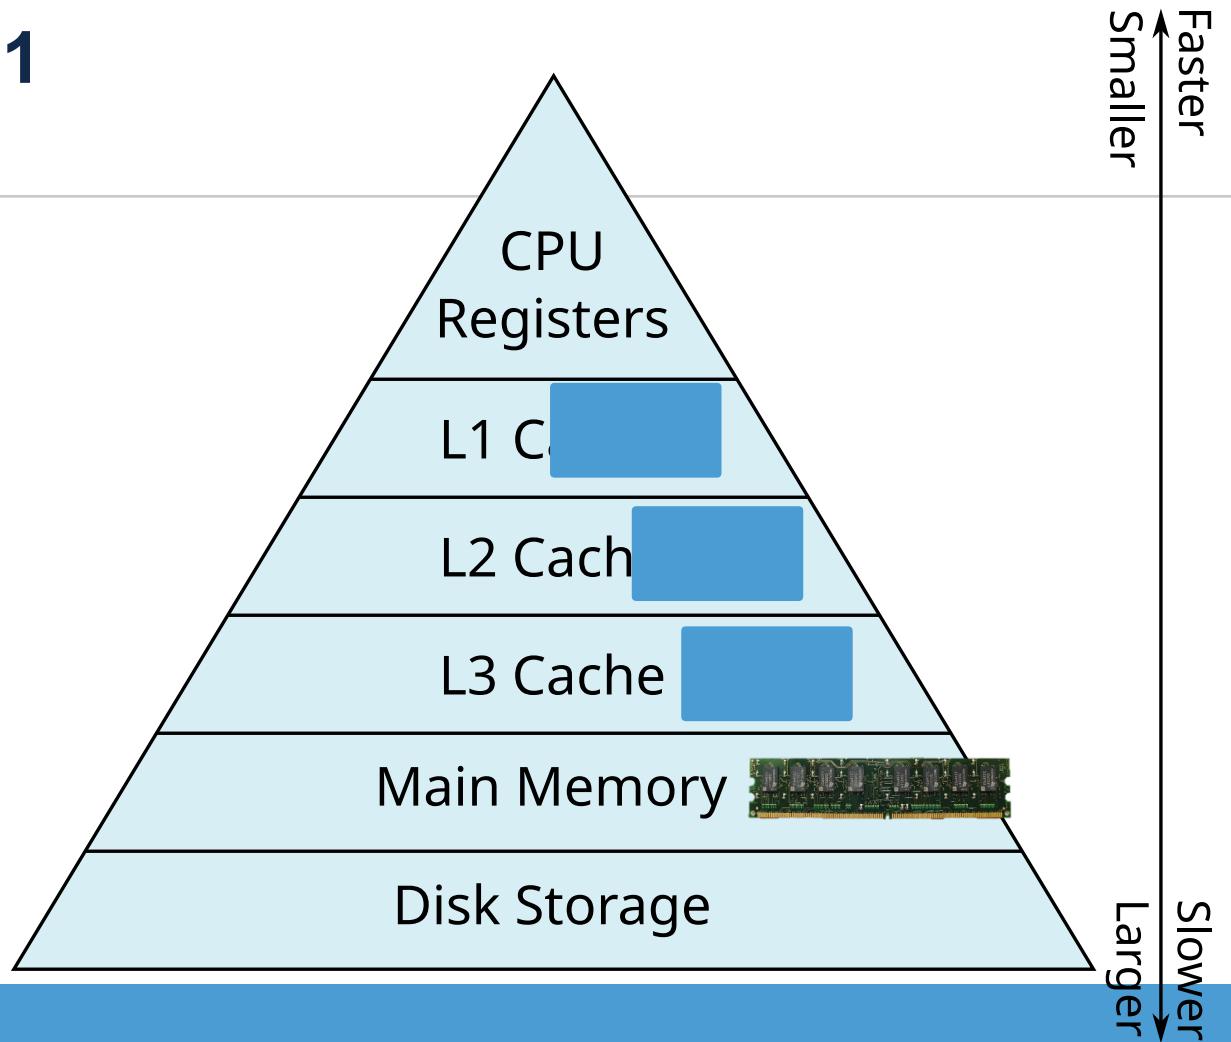

**How can attacker monitor cacheline usage?**

## Attack Strategy #1: Flush+Reload

---

- The flush instructions allow explicit control of cache states
  - In x86, `clflush vaddr`
  - In ARM, `DC CIVAC vaddr`
- What are these flush instructions used for except for attacks?
  - For coherence, in the case when the data in the cache is inconsistent with the data in the DRAM.

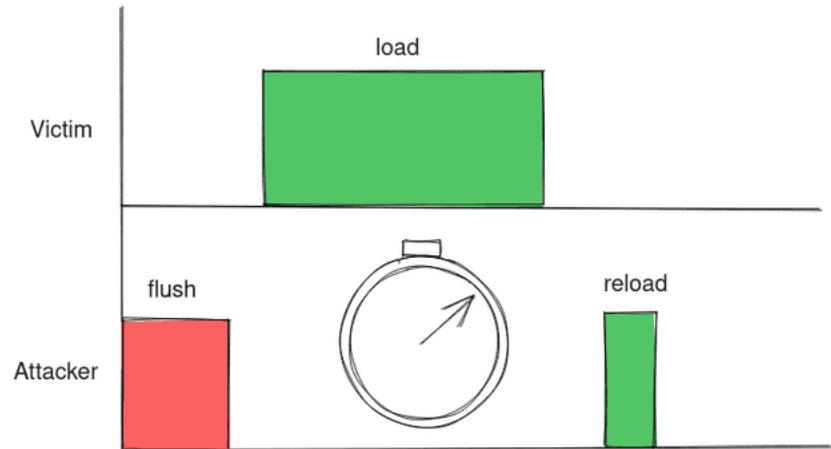

# Caching 101

## Flush+Reload steps

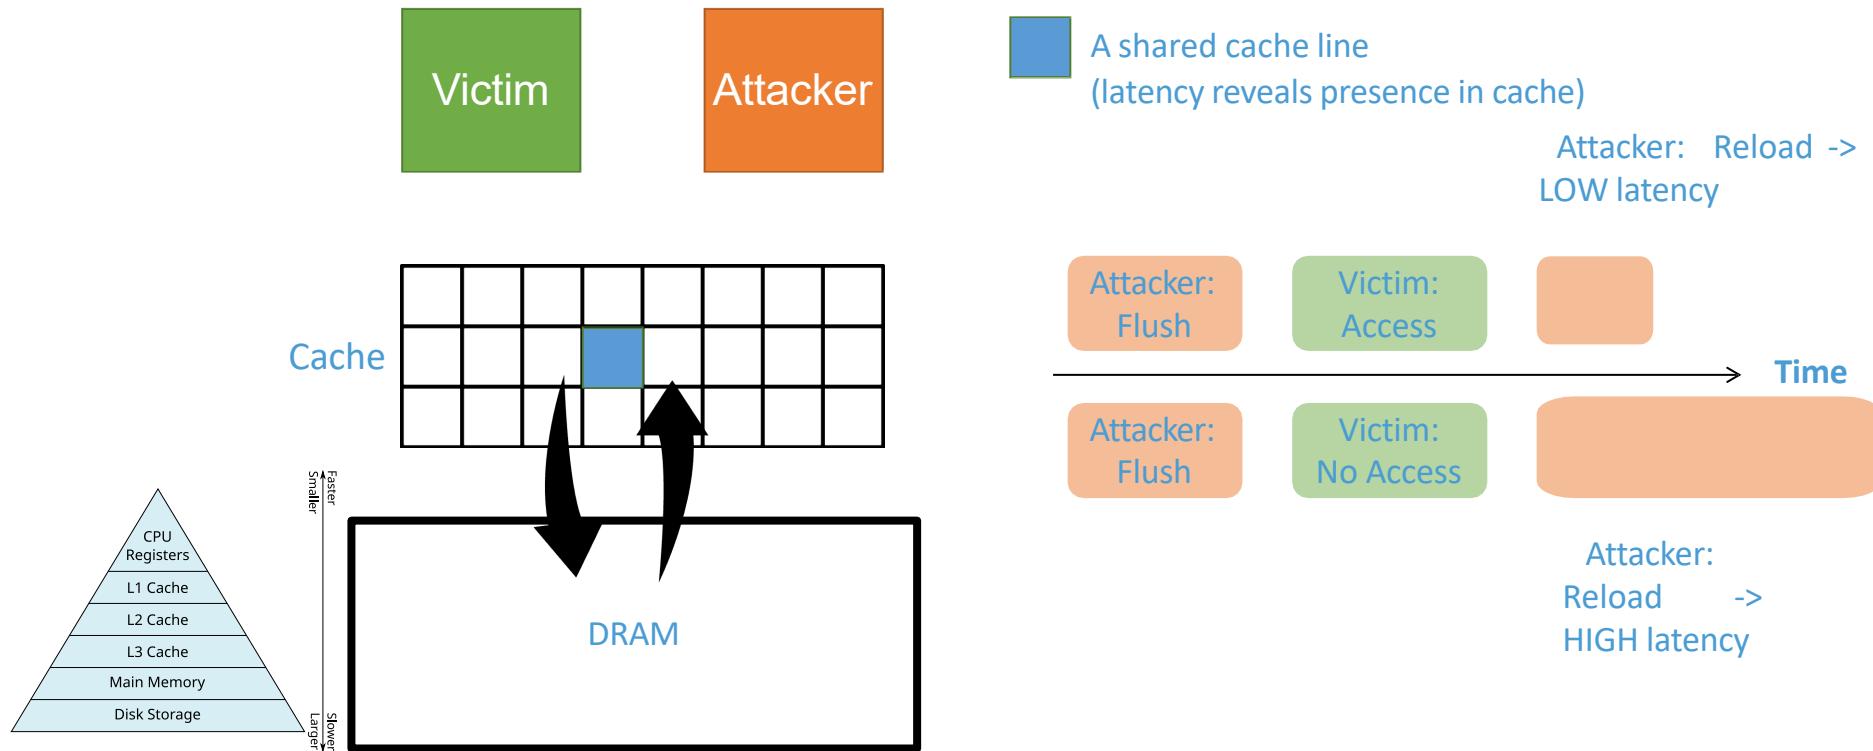

---

1. Attacker flushes shared memory
2. Attacker waits for victim to access (or not) the memory
3. Attacker reloads the cache line
4. Latency reveals whether the victim accessed that cache line

Made with Excalidraw

# Flush+Reload

# Flush+Reload

Attacker

# Cache Lines

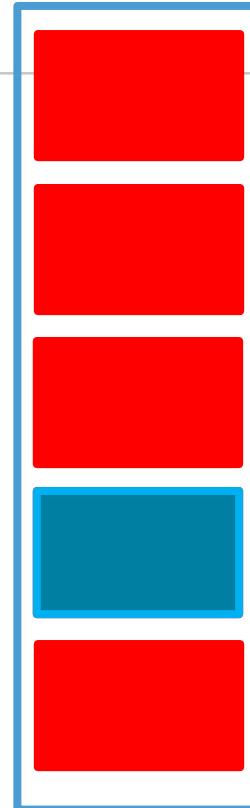

Reload (slow)

Reload (slow)

Reload (slow)

Reload (fast)

Reload  
(slow)

Victim

$a_{0,0}$	$a_{0,1}$	$a_{0,2}$	$a_{0,3}$
$a_{1,0}$	$a_{1,1}$	$a_{1,2}$	$a_{1,3}$
$a_{2,0}$	$a_{2,1}$	$a_{2,2}$	$a_{2,3}$
$a_{3,0}$	$a_{3,1}$	$a_{3,2}$	$a_{3,3}$

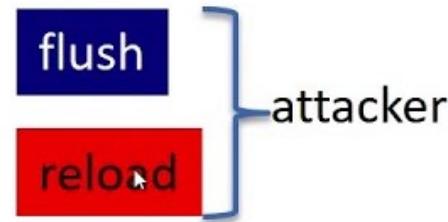

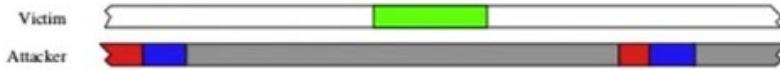

SubBytes

S

$b_{0,0}$	$b_{0,1}$	$b_{0,2}$	$b_{0,3}$
$b_{1,0}$	$b_{1,1}$	$b_{1,2}$	$b_{1,3}$
$b_{2,0}$	$b_{2,1}$	$b_{2,2}$	$b_{2,3}$
$b_{3,0}$	$b_{3,1}$	$b_{3,2}$	$b_{3,3}$

Attacker learns secret byte=3

# Some possible outcomes

access victim

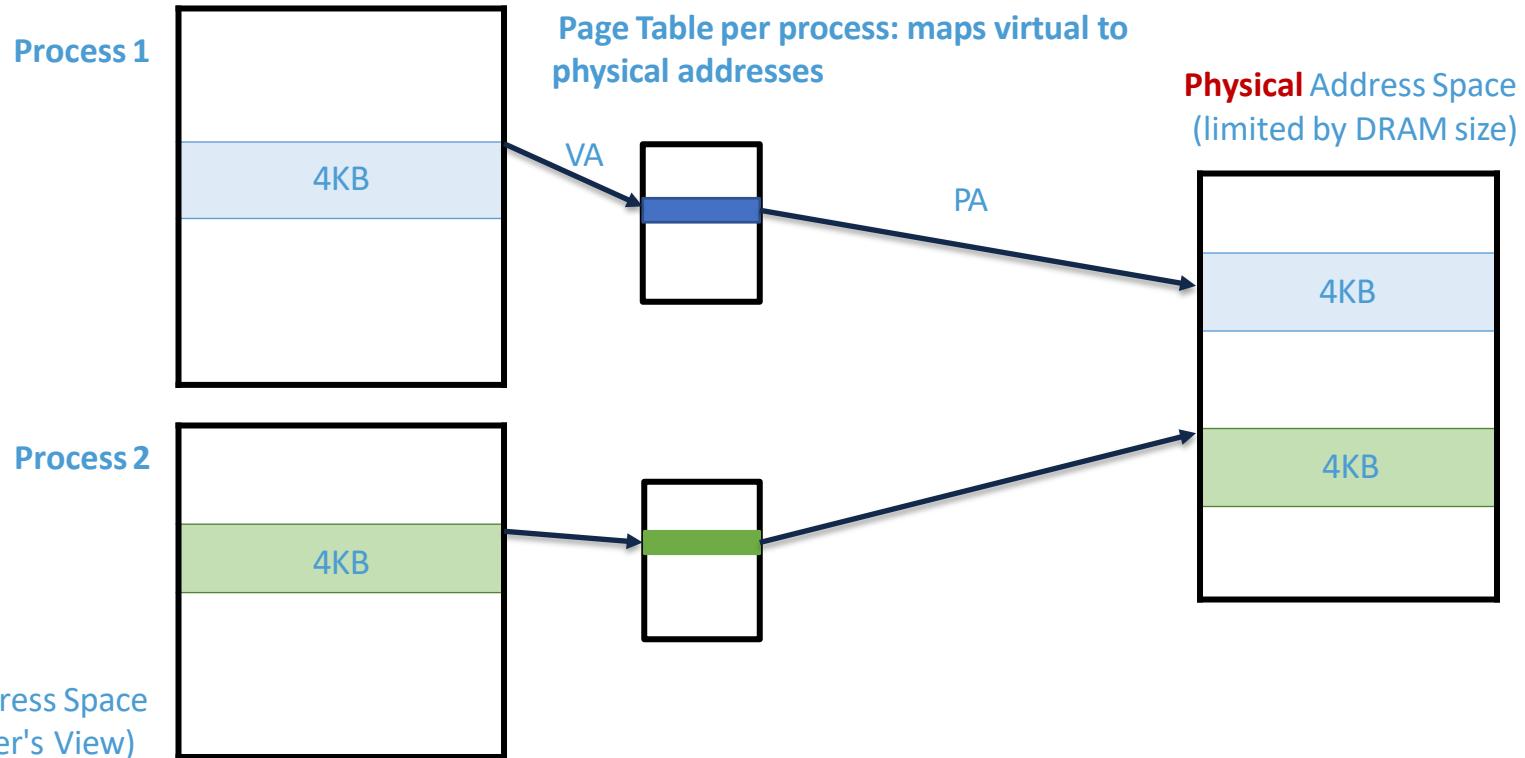

```
r = 1
for i = n-1 to 0 do
    r = sqr(r)
    r      = mod(r, m)

    if di == 1 then
        r = mul(r, b)
    r = mod(r, m)

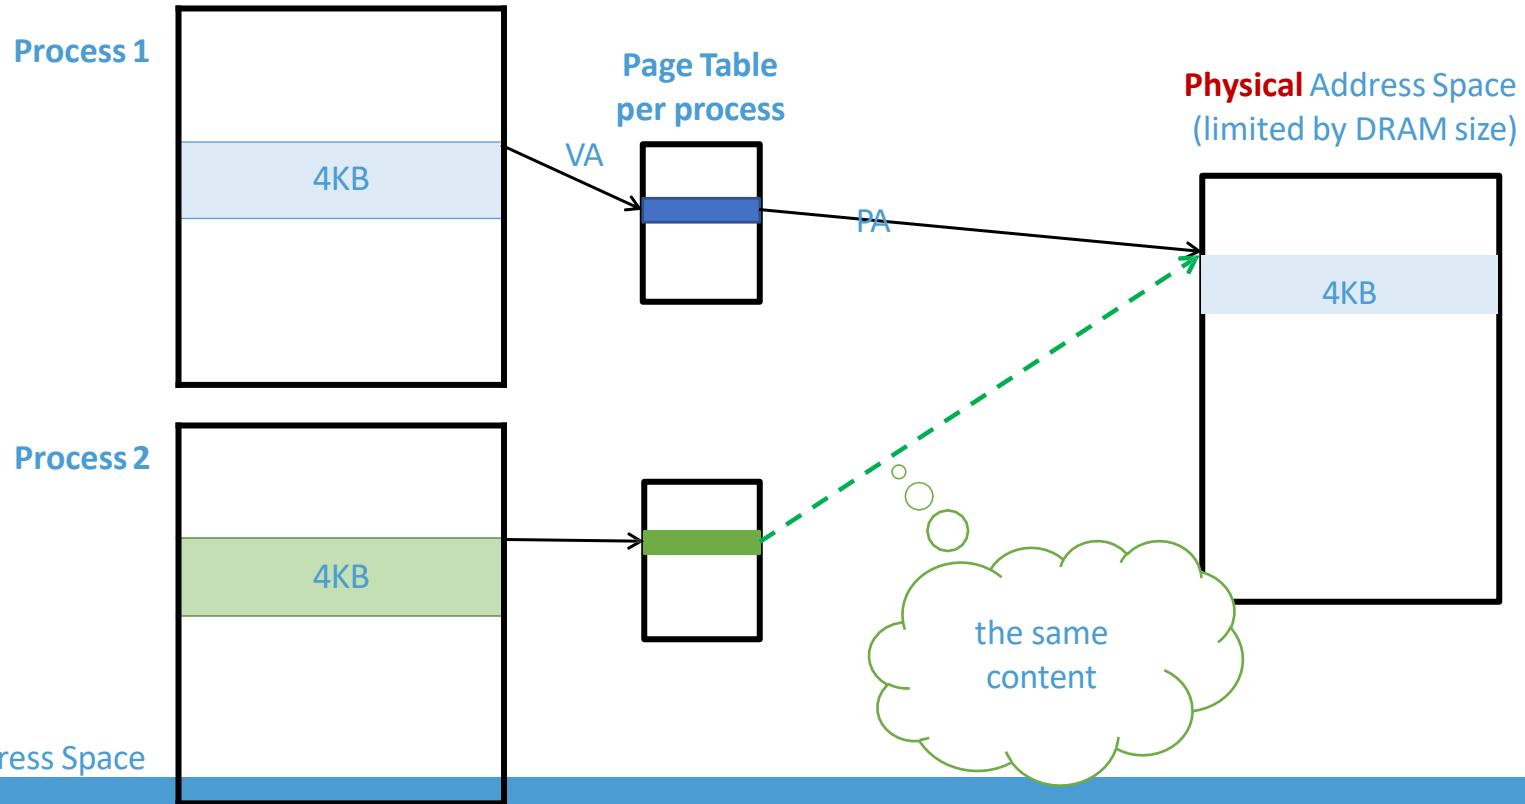

end
```

## **Shared Memory in Practice**

# Page Mapping

# Transparent Page Deduplication

## Attack Strategy #2: ?

---

- Cache state manipulation instructions
  - In X86, `clflush vaddr`
  - In ARM, `DC CIVAC vaddr`
- What if these instructions are not available in user space?
  - Apple devices
  - “*Except ARMv8-A CPUs, ARM processors do not support a flush instruction*”
  - Flush instructions removed from Chrome’s NaCL after Rowhammer

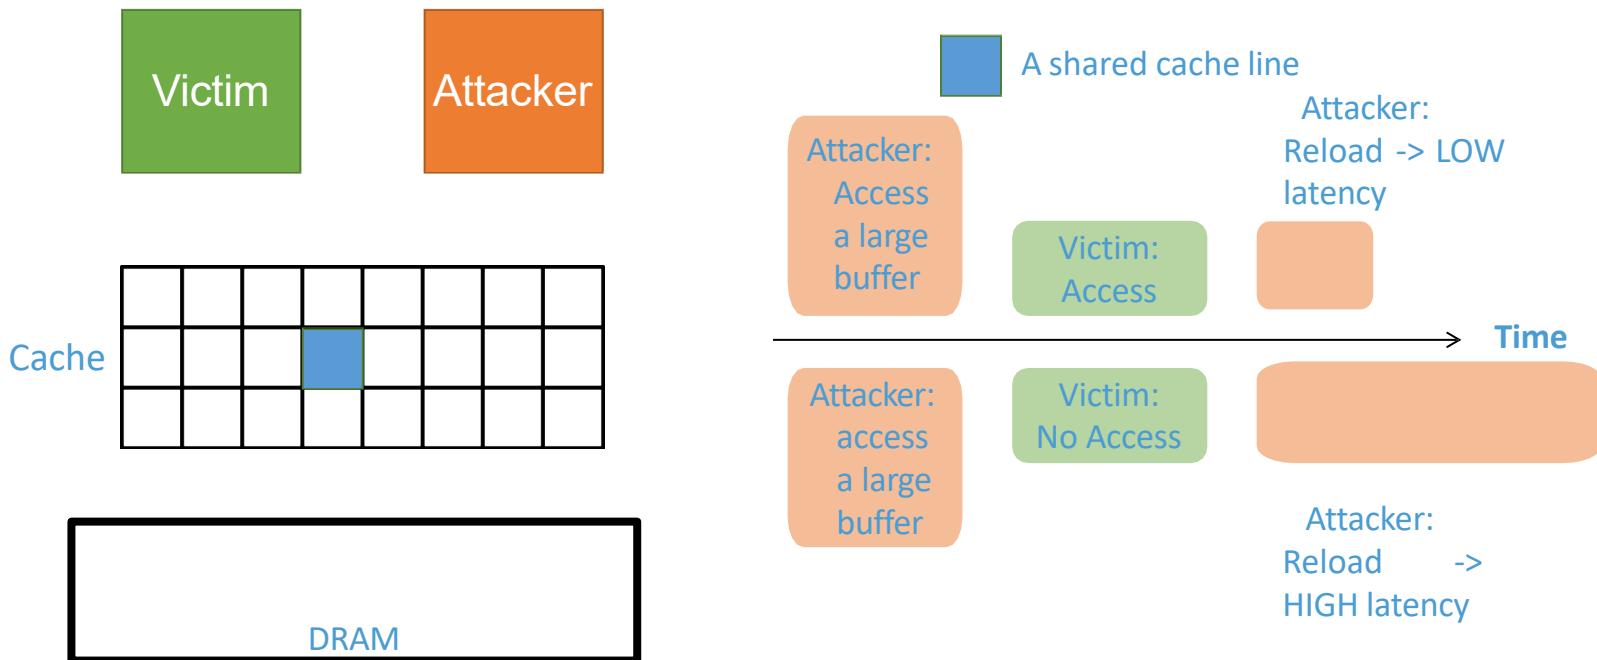

*from ARMageddon: Cache Attacks on Mobile Devices (USENIX'16)*

## Attack Strategy #2: Evict+Reload

---

- If we can't use a flush instruction, force eviction instead
1. Attacker accesses large amount of memory to evict shared memory
  2. Attacker waits for victim to access (or not) the memory
  3. Attacker reloads the cache line
  4. Latency reveals whether the victim accessed that cache line

## Attack Strategy #2: Evict+Reload

# Lessons Learnt So Far

- flush+reload
  - Requires “flush” instruction
- Evict+reload
  - Doesn’t require “flush”

The fundamental problem:  
**shared memory** between  
different security domains.

### ▼ Details

This article acknowledges the recent academic research that leverages Transparent Page Sharing (TPS) to gain unauthorized access to data under certain highly controlled conditions and documents VMware’s precautionary measure of restricting TPS to individual virtual machines by default in upcoming ESXi releases. At this time, VMware believes that the published information disclosure due to TPS between virtual machines is impractical in a real world deployment.

Published academic papers have demonstrated that by forcing a flush and reload of cache memory, it is possible to measure memory timings to try and determine an AES encryption key in use on another virtual machine running on the same physical processor of the host server if Transparent Page Sharing is enabled between the two virtual machines. This technique works only in a highly controlled system configured in a non-standard way that VMware believes would not be recreated in a production environment.

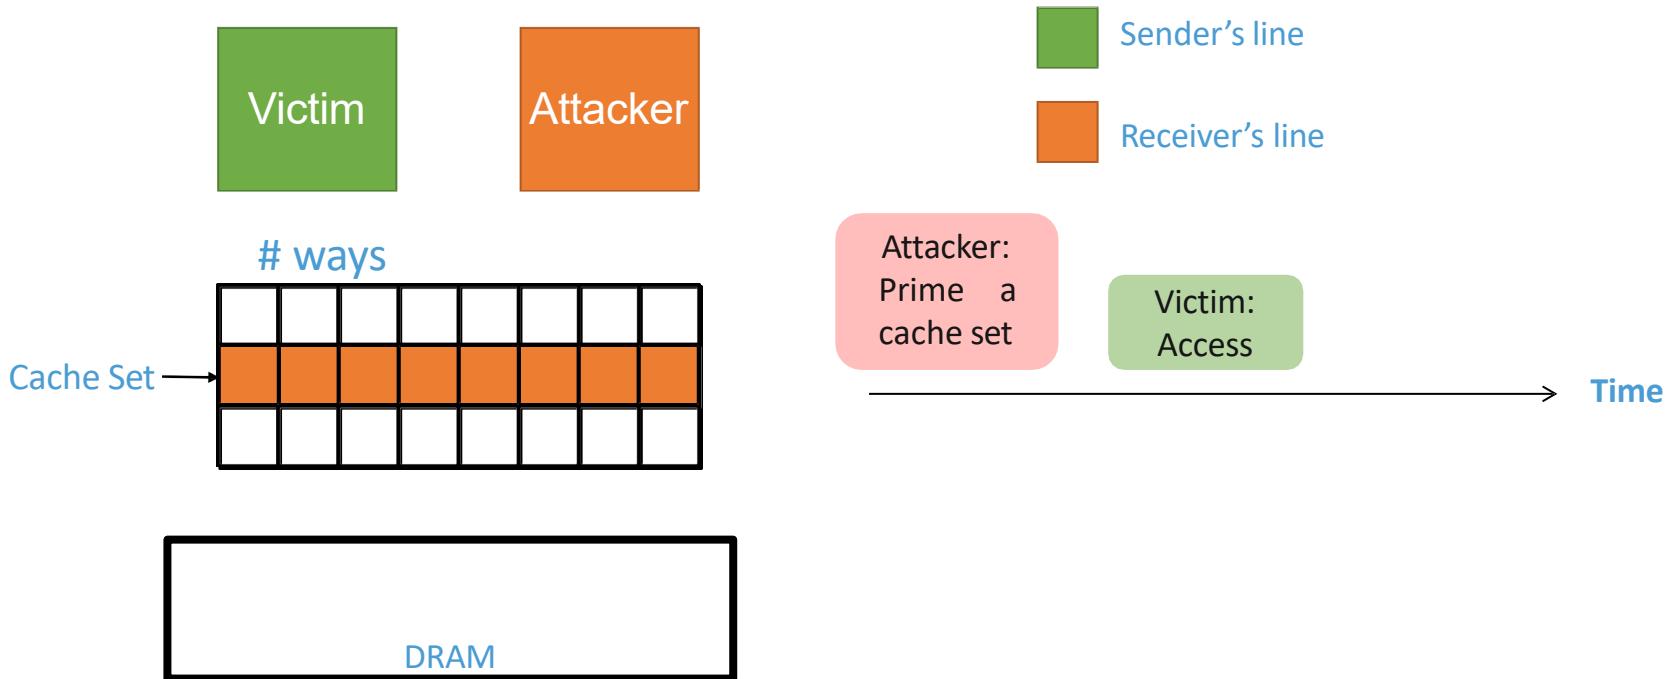

Even though VMware believes information being disclosed in real world conditions is unrealistic, out of an abundance of caution upcoming ESXi Update releases will no longer enable TPS between Virtual Machines by default (TPS will still be utilized within individual VMs).

## Attack Strategy #3: Prime+Probe

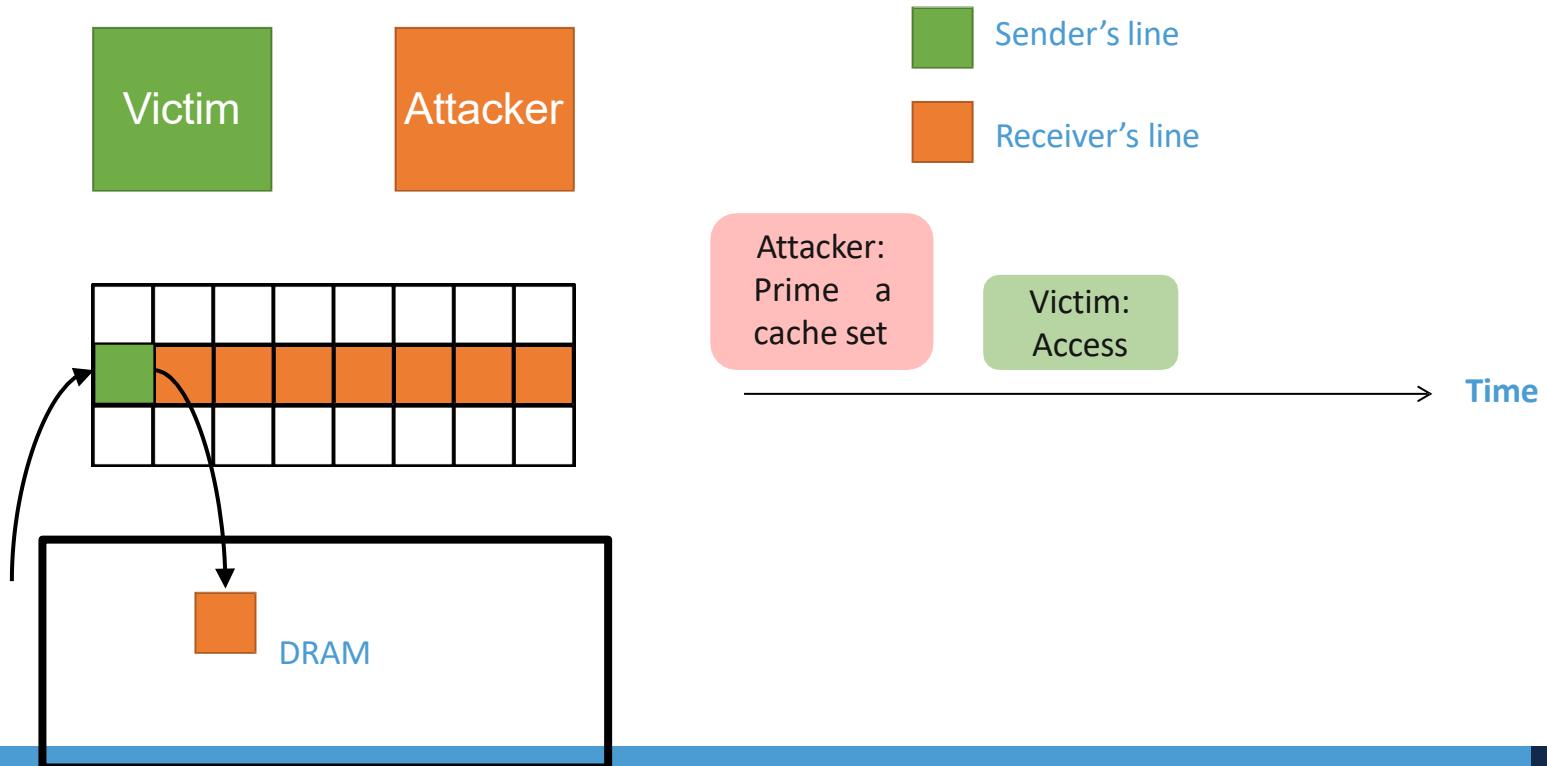

---

- Removes requirement of shared memory
1. Attacker “primes” a cache-set by accessing A elements in the cache-set
    - Called an eviction set
  2. Attacker waits for victim to access (or not) the memory
  3. Attacker reloads each cache line
  4. Latency reveals whether the victim accessed that cache line

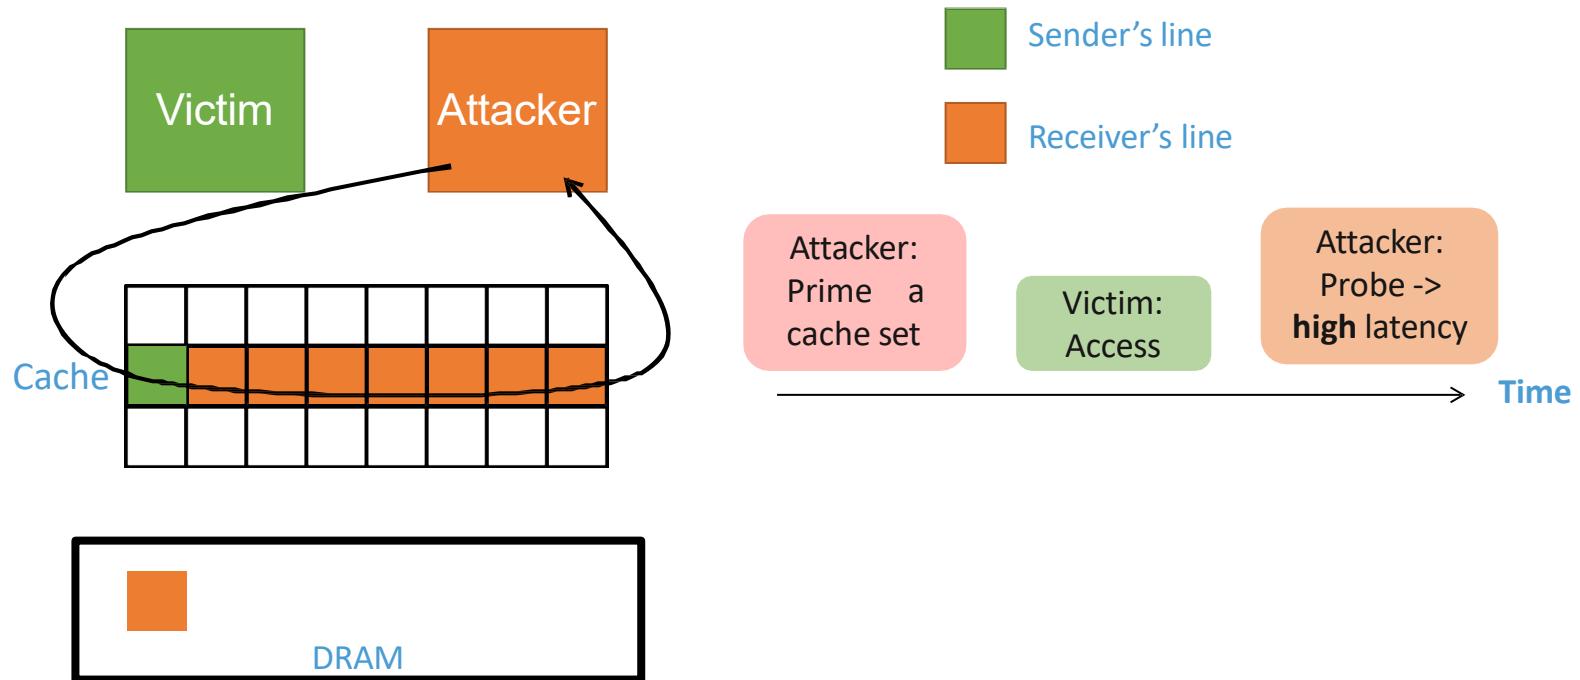

## Attack Strategy #3: Prime+Probe

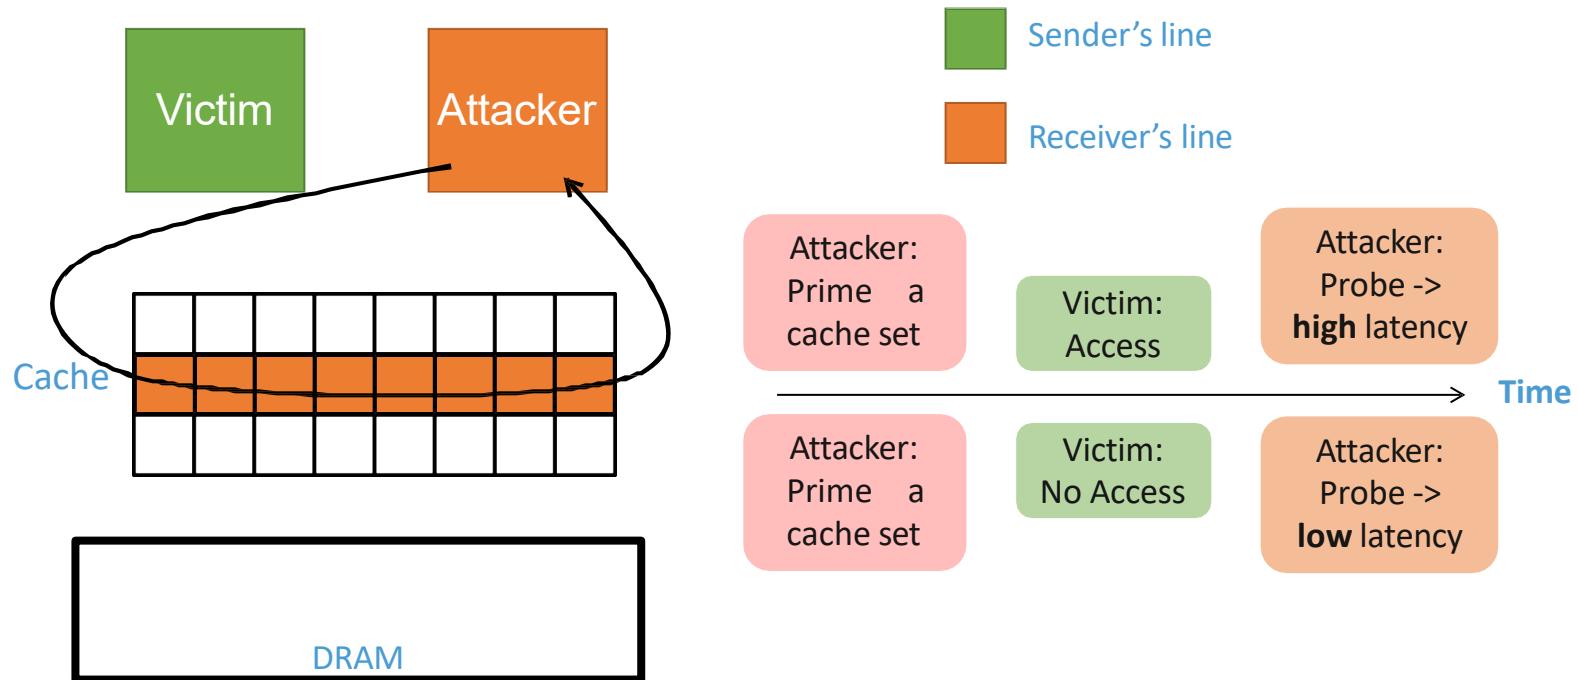

## Attack Strategy #3: Prime+Probe

## Attack Strategy #3: Prime+Probe

## Attack Strategy #3: Prime+Probe

# Timing Code

---

```
lfence  
mfence  
rdtsc  
mov %eax, %edi  
mov (<vaddr>), %rsi  
lfence  
rdtsc  
sub %edi, %eax
```

In x86, 8 GPR:

- `rax, rbx, rcx, rdx`
- `rsp, rbp`
- `rsi, rdi`

*"r" means 64-bit*

*replacing "r" with "e" means the lower 32 bits.*

**rdtsc:**

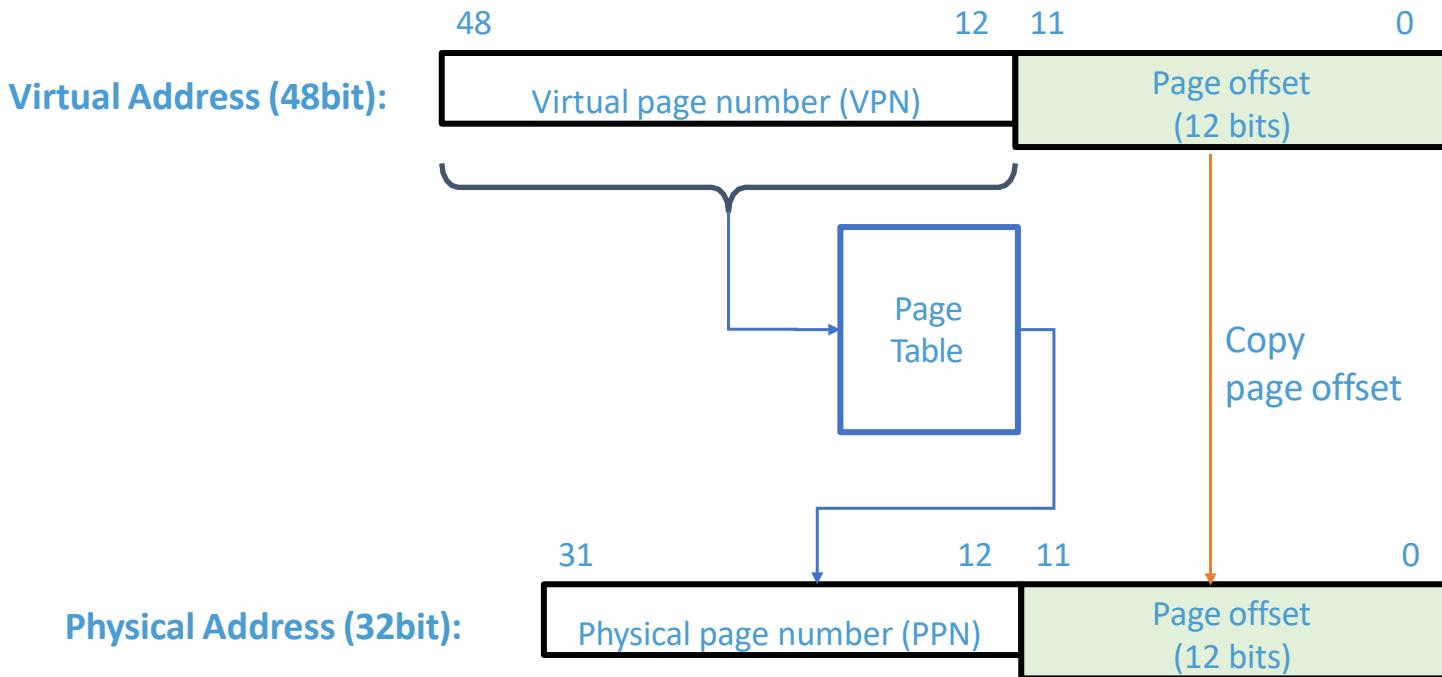

- Read Time-Stamp Counter
- `edx:eax := TimeStampCounter;`

**lfence:**

- Load Fence
- Performs a serializing operation on all load instructions

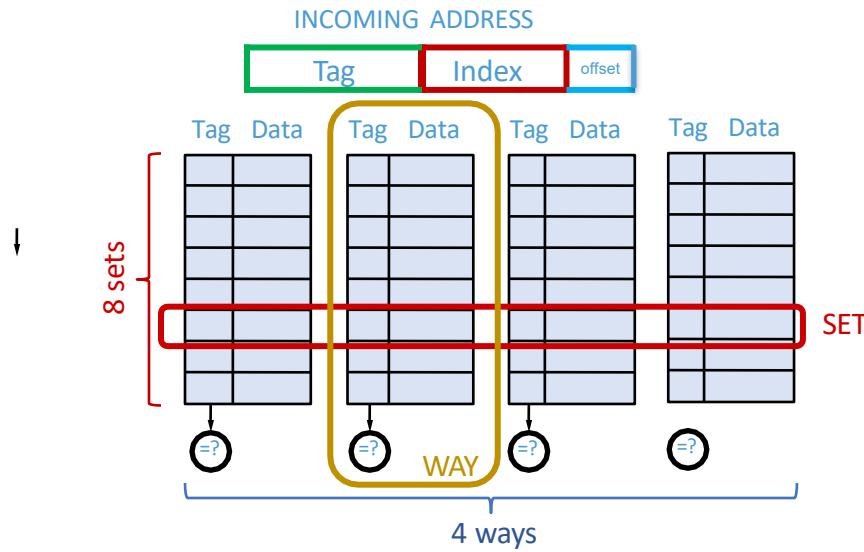

## More Background

# Address Translation (4KB page)

# N-way Set-Associative Cache

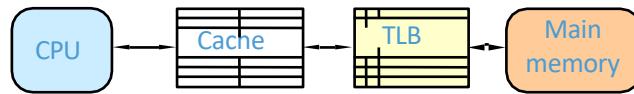

- Does cache use virtual address or physical address?

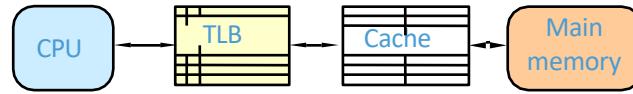

# Using Caches with Virtual Memory

---

*Virtually-Addressed Cache*

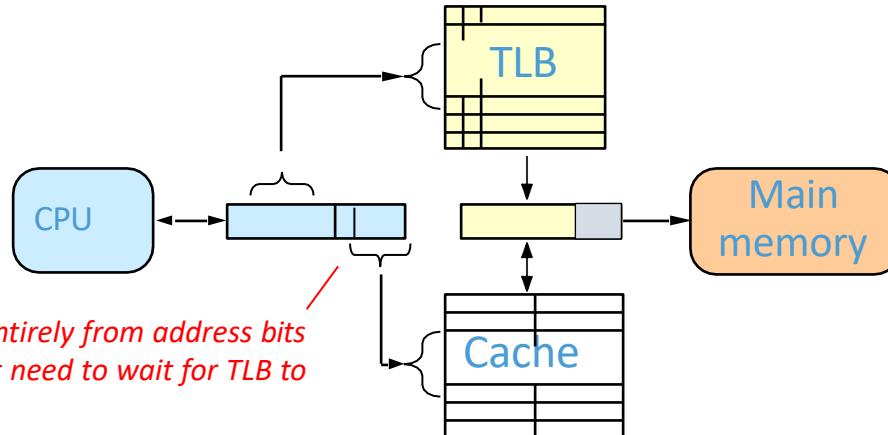

*Physically-Addressed Cache*

- FAST: No virtual  $\rightarrow$  physical translation on cache hits
- Problem: Must flush cache after context switch

- Avoids stale cache data after context switch
- SLOW: virtual  $\rightarrow$  physical translation before every cache access

# Best of Both Worlds (L1 Cache): Virtually-Indexed, Physically-Tagged Cache (VIPT)

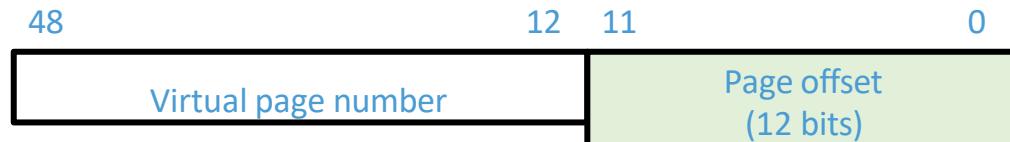

# Using Huge Pages

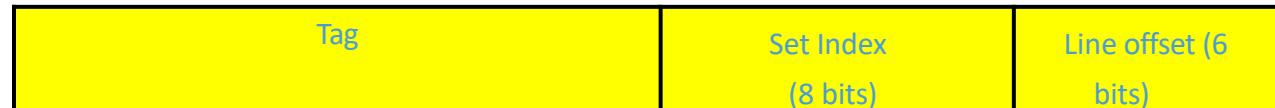

---

- Huge page size: 2MB or 1GB

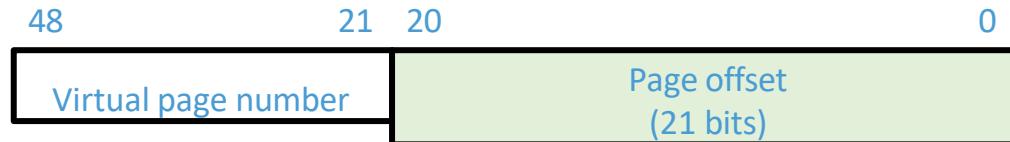

Virtual Address :  
4KB page

Cache mapping:  
(256 sets)

Virtual Address :  
2MB page

# Quiz!

---

- I have a virtual address: 0xAAAA
- The cache parameters are as below
  - Cache size: 32KB
  - Line size/Block size: 64B
  - Associativity: 8

**Question 1:**

What is the cache set index?

**Question 2:**

What is the next address that map to  
**the same cache set** as this one  
but not the same cache line?

## Takeaways

---

- Practical challenges in implementing a reliable cache attack
  - Page sharing
  - Uncertainty due to page mapping
  - Replacement policy
  - Etc.
- Hardware and software optimizations make attacks easier
  - Transparent page sharing
  - Copy-on-write
  - Huge pages
  - Virtually-indexed and physically-tagged caches
